

## Project Update: September 2009

The project site was surveyed with team members and local communities. We have observed that pangolin species participated in the forest ecosystem and nature biodiversity balance by eating overpopulation of termites and ants.

To improve the local people's interest and in-kind support to wild pangolin conservation project, during the whole project period we have conducted various public extension activities as mentioned in the formal proposal.

On balance, to encourage the present of wild pangolins, we have conducted this community-based pilot project. These works motivated many school children to participate in their ecosystem health works in and around the project area.
