

## roject Update: July 14

The project has been focalized in the production of plants in nursery. We are reproducing 6000 *P. glomeratus* and 3000 *P. lanata* plants obtained of cuttings and seedlings collected from the forest.

The harvest of seeds was not possible because we did not find seed trees. We have carried out interviews of farmers of communities and officials of municipal government in order to understand the strengths and weaknesses to compliance of local norms. Radio programmes are being produced about some of these topics identified and this month will start the spread. The workshops with communities started in order to inform the project objective and to plan work activities. Currently, we are identifying with them the principal problems to manage the forest with participative tools. Monitoring of reforested plants in previous RSG projects were carried out and one experiment of reforestation of *P. glomeratus* in different microhabitats was implemented.

Evaluation of the reforested plant higher of *P. glomeratus*
