

Project Update: August 2014

The field part of the project has successfully finished. We have found and investigated a number of populations of the target plant species. For example, we have found a new northernmost locality of *Magnolia hypoleuca* on the cape Dokuchaeva and previously unknown large population of *Hydrocotyle ramiflora* in the central part of the island. As an additional result we have found new plant species for the island Kunashir and for the nature reserve Kurilsky – aquatic spore-bearing plant quillwort (*Isoetes asiatica*). Our field work was described on the website of nature reserve Kurilsky (<http://kurilskiy.ru/news/post/524>) and by local mass media Sakhalin Info (<http://www.sakhalin.info/news/15.08.2014/95360>) and Sakhalin Media (<http://sakhalinmedia.ru/news/island/15.08.2014/379339/probelikrasnoy-knigi-rossii-zapolnyat-rabotayuschie-na-kurilah-botaniki-iz-moskvi.html>).

Now we are processing our data and preparing publication in scientific journal and material for new edition of the Red book of Sakhalin region and Russia.
