

Project Update: August 2017

We have started to make transects to determine the structure and composition of the vegetation in the riparian strips of the cloud forest. So far, we completed seven sites. We have two mist netting sites left to conclude the bird capture for the project.

One of the measures that we take in the riparian remnants of cloud forest is the canopy cover, using a spherical densiometer.

In addition, we recorded other vegetation parameters such as the DBH (Diameter at breast height).
