

## Protected Areas for manatees (*Trichechus inunguis*) in the Colombian Amazon

Sarita Kendall Casimiro Ahue Luis Hernando Peña

Fundación Natiutama, Puerto Nariño, Amazonas, Colombia

### Introduction

The Amazonian manatee (*Trichechus inunguis*) is still hunted throughout its range, although the species is protected by law in all Amazon countries. Loss of habitat and incidental captures by fishermen – particularly of calves – also endanger manatees. With a difference of about 10 meters in the water level between the high and low water seasons, manatees in most areas have annual migration patterns when exposed them to different threats at different times of year. Detailed seasonal migrations were established for the Puerto Nariño area of the Colombian Amazon by observation and feeding evidence, with more than 1600 manatee sightings between 2002 and 2008. At the same time, the conversion of manatee hunters into guardians of the species and an extensive community education program vintage 2004 has resulted in hunting, with 122 calves recorded since 2004.

### Migrations and Priority Areas

Areas with strong manatee presence (more than 15% of sightings for that season) were defined as Priority Areas and are shown by a manatee, while areas with >5 calf sightings are represented by a calf. The migration pattern from the inner lakes to the River Amazon is well-defined, with only occasional sightings in other areas.

Percentage of sightings by habitat and season 2002-2008

Area	High water	Rising water	Low water	Rising water
Inn. lakes	52.7	21.9	3.0	21.9
Outer lakes	2.6	1.6	4.5	37.6
River Amazon	0.2	5.7	82.4	2.6

**High water season – Inner lakes & Tingoito headwaters**  
Manatees are dispersed over a very wide area during the flood season. They move into the flooded forest and distant bays, where there is abundant aquatic vegetation available. The main threat to the manatees is the closure of channels by (illegal) traps and fishing nets at the beginning and end of the high water season. Light nets sometimes trap calves. In 2007-2008 two fishermen freed calves from the nets. A very few manatees stay in the deeper lakes through the year, making them more vulnerable to capture in the dry season.

**Rising and falling waters – Tingoito-Cenote Lakes**  
Manatees gather in these areas before moving on to the River Amazon. Up to 14 manatees have been observed in one area, mostly boats have been recorded, as well as new-born calves during rising waters. The manatees are highly visible as they move along narrow channels and wait the next stage of migration out to the river (rising water) or into the flooded land (rising water). Counts carried out by six fishermen-co-monitors during rising water recorded 20 manatees in November 2008. Threats include fishing activity and boat movements entering Tingoito Lake for dolphin watching. In addition, manatees have to pass the town of Puerto Nariño along a narrow bypass with considerable boat traffic.

### Low water – River Amazon

Space restricted and manatees are found in the backwaters that form rivers and islands. There is little food available along the river banks in summer – small patches of grasses and decomposing logs – and the animals appear to choose places where the current is minimal so they can conserve energy. As the islands and beaches change each year, the backwaters available to manatees change too. Between 1 and 11 manatees have been recorded in a single backwater, with the total rising to a maximum of 14. They are highly exposed to boat traffic and to fishing activity, using both large and small nets. Calves are particularly vulnerable, every year one to two calves are captured in fishing nets. Occasionally manatees are hunted by fishermen on the Peruvian side of the River Amazon; no measures have been taken by the authorities.

### Protected areas and the conservation of manatees

The area around Puerto Nariño is not a protected area, but the lakes are included in the territory of an Indian Reserve. The agreement with local fishermen to protect manatees is a social agreement, monitored by monitoring and constant education work in schools and communities. Elsewhere in the Amazon, the nature of these "Protected Areas" depends on negotiations with local authorities and communities.

### Acknowledgements

We would like to thank the numerous individuals who have resulted in the protection of manatees, especially the Amazon and Defense forces, the Indian and Municipal authorities of Puerto Nariño; the communities in the area; Corporación Pájaro Small Grants Foundation; and the Columbus Zoo and Aquarium Conservation Fund for ongoing support.
