## **1.0 Introduction**

Honeybees (*Apis mellifera*) are eusocial insects of the genus *Apis*, distributed worldwide. Honeybees are essential insects, due to the benefits of their products and services for humans and environment management. Recently, there is increasing in reported cases of honeybees' colony decline globally while habitat loss and effects from climate change are mainly reported culprits (Goulson et al 2015). The loss of honeybees, which are acknowledged as important pollinators of both wild and cultivated plants, has an impact on the improvement of livelihoods, food security, biodiversity, and ecosystem health (Dietemann et al. 2009; Potts et al. 2010). The survival of this key insect depends much on potential plants that offer resources such as nectar, pollen, and resins, however, regardless of depending on plants for survival, honeybees are selective and show a preference for plant species over others in a landscape (Sajwani et al. 2014). Therefore, the idea of knowing the plants preferred by bees in a particular landscape is inevitable for bees' conservation and persistence.

Most of beekeeping potential areas in Tanzania the knowledge and information on available plants for honeybees and their preferences is overlooked. This project, therefore, aimed to provide scientific information on plant diversity and honeybees' foraging preferences across two rain seasons (short and long rain) of 2021/2022, with the intention of conserving plants and honeybees. During assessment of the flowering plant diversity and honeybees' foraging preferences, the study was conducted in two different rain seasons, the short rain season (November to January) and the long rainy season (February to May), in two study areas. The gathered information from the current study paves a way for other studies and provide scientific baseline and information on the honeybees foraging ecology and plant abundance in a landscape, which is potential information in conservation of both plants and honeybees. However,

the information is important in the beekeeping industry, which is reported to employ many people especially in low-income countries.

**Figure 1:** Study areas (I) and (II) in Same district, where the assessment of honeybees' plant diversity and foraging preferences were conducted in both short and rain season of 2021/2022.

## **2.0 Reconnaissance**

The survey conducted to all the previously identified areas by purposive sampling, the criteria considered during selection of the study areas were the areas that bordering to Mkomazi National Parks and Forest reserves and the areas where beekeeping activities are conducted by the local people and being supported by Mkomazi National and Same District Council. Among other factors for site selection, the wards that bordering to national park and other protected areas were highly considered. This was done with the objective of promoting ecosystem health through conservation since the persistence of honeybees in these places would have a positive effect. In addition, the existence of honeybees in these areas would stimulate beekeeping activity, which is friendly to the environment, and reduce human engagement to anthropogenic activities that can have negative impact to environment and ecosystem in general.

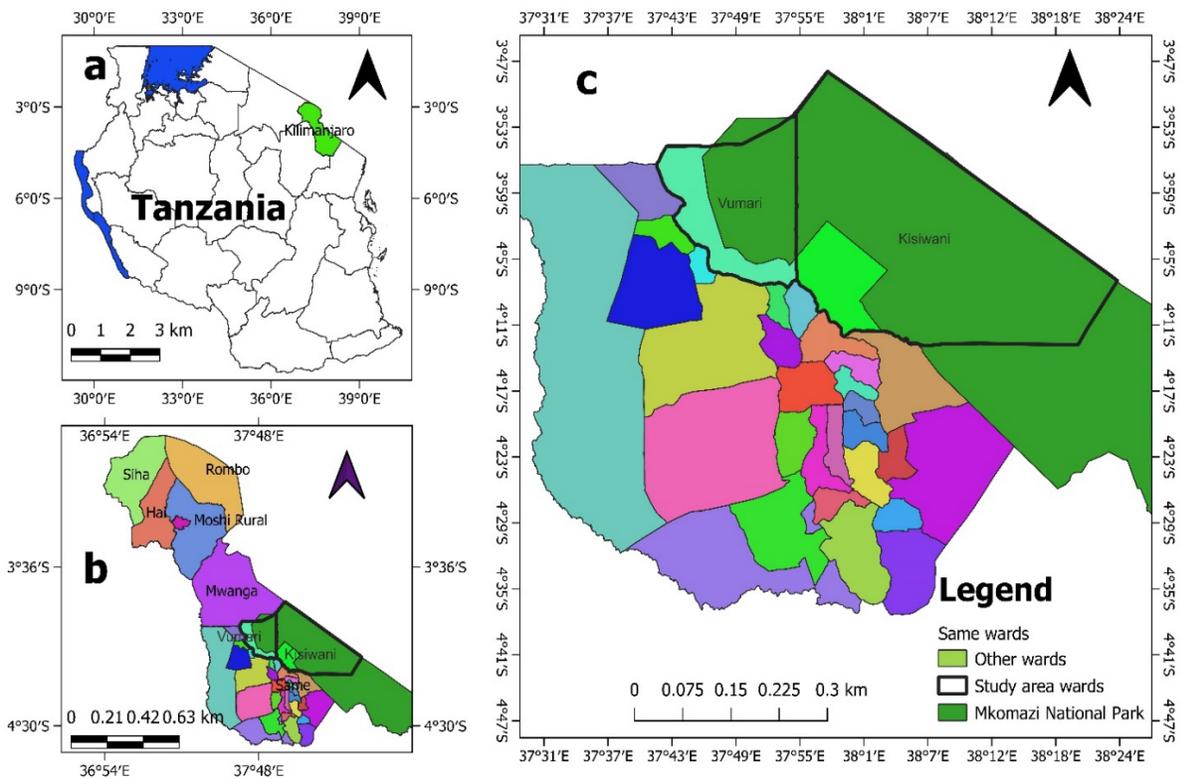

**Figure 2:** Reconnaissance survey at different study areas before data collection

**3.0 Study Site Description and Justification**

The study areas were located in Same district, Northern Tanzania, in two wards of Kisiwani (-4.147426/37.9811853) and Vumari (-4.0235862/37.7219419) where beekeeping activities are conducted alongside the Mkomazi National Park boundaries. The district is bordered to the north by Mwanza District, to the northeast by Kenya, to the south and southeast by Tanga region, and the west by Manyara region. The areas experience annual rainfall ranging from 1000 to 2000 mm, which is divided into two seasons, a short rain season occurs between November and January while, a long rain season start from February to May (Prins and Loth 1988). The main economic activities in the areas are agricultural

where people involve in both commercials by cultivating sisal and food production, besides agriculture, tourism is mentioned to be among other growing economic activities (Mwanyoka and Lopa 2016). Tourism activity in Same district prompted by the existence of Mkomazi National Park and other protected areas like Chome and Shengena forest reserves.

The project areas were selected purposively, firstly, the two areas are bordering to Mkomazi National Park which is a home of most endangered species like Rhino and the wild dogs. Secondly, the National Park through community development unit, supports beekeeping activities by providing facilities to individuals and training. The promotion of beekeeping in those areas should therefore go hand in hand with ensuring the existence of honeybees, which is prompted by the availability of enough plant resources.

**Figure 3:** The diagrammatical representation of the study area, showing Tanzania (a), Kilimanjaro region (b), and wards (c) where the study was conducted in 2021/2022.

### **3.1 Data collection**

Field observations were conducted to assess flowering plants' diversity and honeybees' foraging preferences during short (November 2021-January 2022) and long (February-May 2022) rain seasons. The transect method was used for plant diversity assessment as per (Ashton & Macintosh, 2002), with minor modifications. Two study areas with at least thirty (30) occupied beehives were selected from two different areas about forty (40) km apart in Same district. In each area, two crosscutting transects of at least five (5) km each were established with beehives at the center; twenty (20) points spaced at 0.5 km were established along two transects. At each point, two quadrats of 5 m x 5 m (shrubs and forbs) nested with 1 m x 1 m (grasses) were systematically established on each side of the transect at 50 m from the transect to make forty (40) 5x5m and forty (40) 1x1m quadrats making a total of eighty (80) quadrats (N=80) at each study area per season. All shrubs, forbs, and grasses in these quadrats were identified and counted with the help of a botanist and field guide.

**Figure 4:** Data collection in both study areas across the short and long rain seasons of 2021/2022

The quadrates established for plant diversity assessment were used for honeybees' foraging preference by randomly selecting quadrates that contained blooming plants during the study period. The observation was conducted from 8:00 am to 11:00 am and 4:00 pm to 6:00 pm (Lázaro, Jakobsson, and Totland 2013; Mallinger and Prasifka 2017). The observation involved recording the number of honeybee visits per flower per time (Arroyo, Armesto, and Primack 1985). Four people were involved in counting the number of honeybees' visits to different plant flowers in a specific quadrat. The observation time at each quadrat of interest lasted for 5 minutes (Abrol 2006).

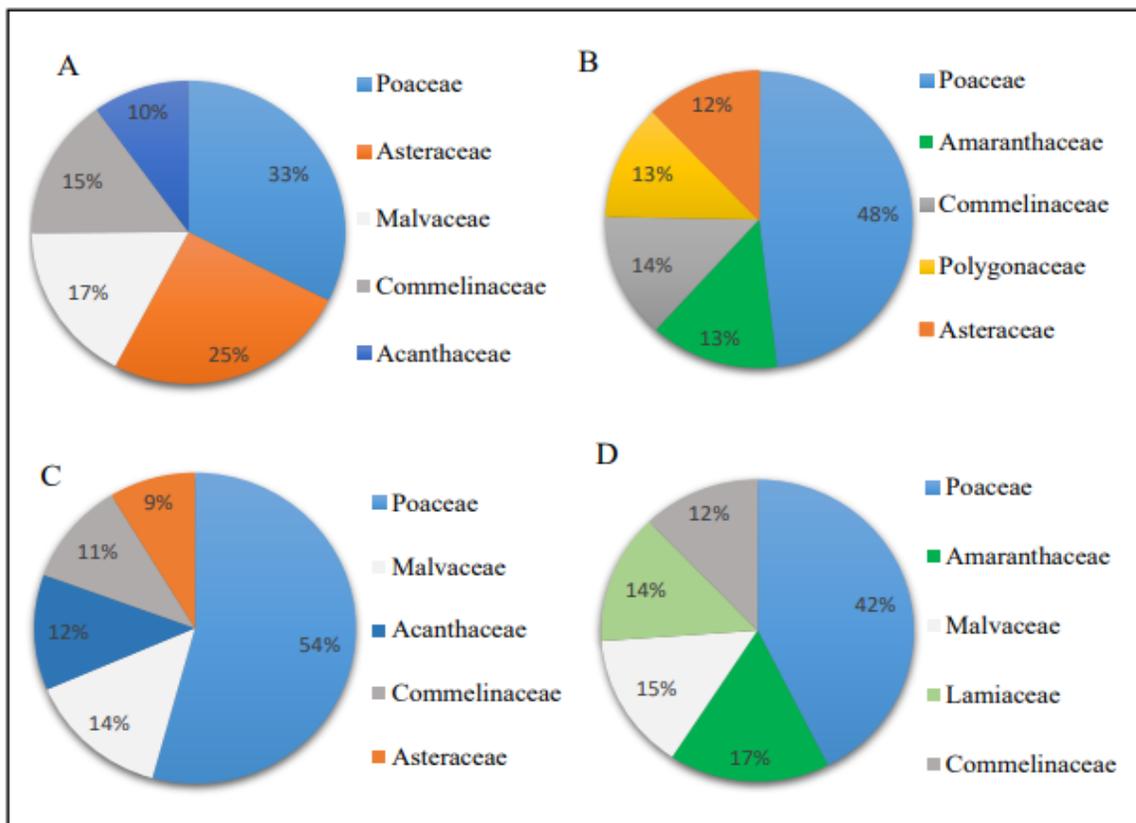

**Figure 5:** Honeybees' flower visitations on different plant species, a) *Hoslundia opposita* b) *Cordia monoica*, c) *Oxygonum sinuatum* and d) *Aspilia mosambicensis*.

#### **4.0 Results on Plant Diversity and Honeybees Foraging Preference**

During data collection, we found different observations regarding plant diversity and honeybees' foraging preferences. There was a significant difference in plant diversity in the study areas across the seasons. The long rain season outstand in the plant availability and abundance comparing to the short rain season in both study sites. This result shows that the long rain season is very potential especially for beekeeping as the availability of foddors/food for honeybees was higher compared to the short rain season. Different plant

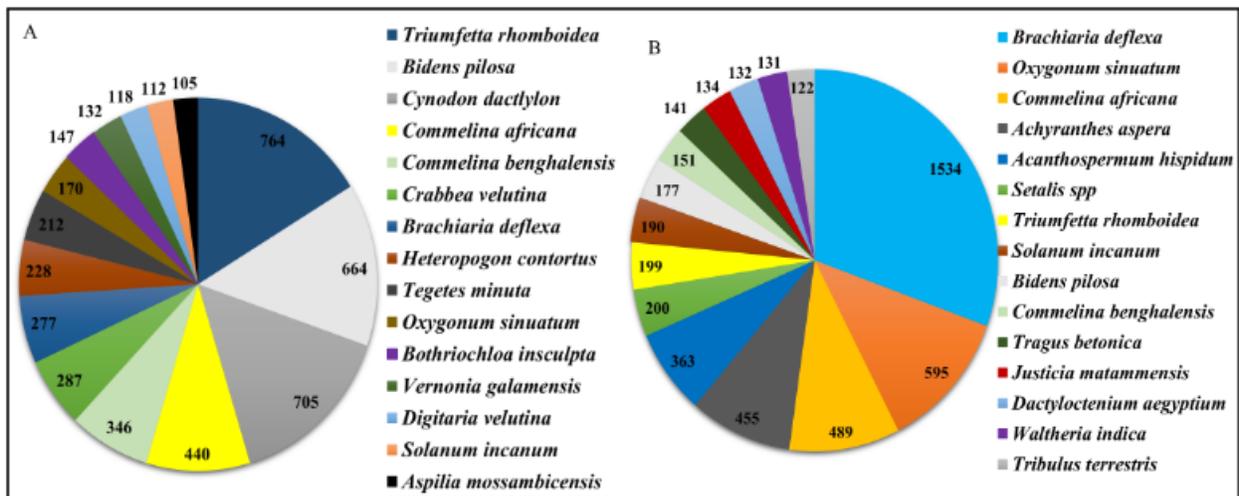

species from various families were recorded in the study areas across the rainy seasons.

In Vumari ward, 42 and 47 plant families were recorded in long and short rainy seasons, respectively; in contrast, for Kisiwani ward, a total of 52 and 41 plant families were recorded during short and long rainy seasons, respectively. During the short rainy season, the most dominant plant families in both study areas were *Poaceae*, *Malvaceae*, *Commelinaceae*, *Acanthaceae*, *Amaranthaceae*, *Polygonaceae*, and *Asteraceae*. Likewise, during the long rainy season, the most dominant plant families in both study areas were *Poaceae*, *Malvaceae*, *Acanthaceae*, *Commelinaceae*, *Amaranthaceae*, *Lamiaceae*, and *Asteraceae* (Fig. 6).

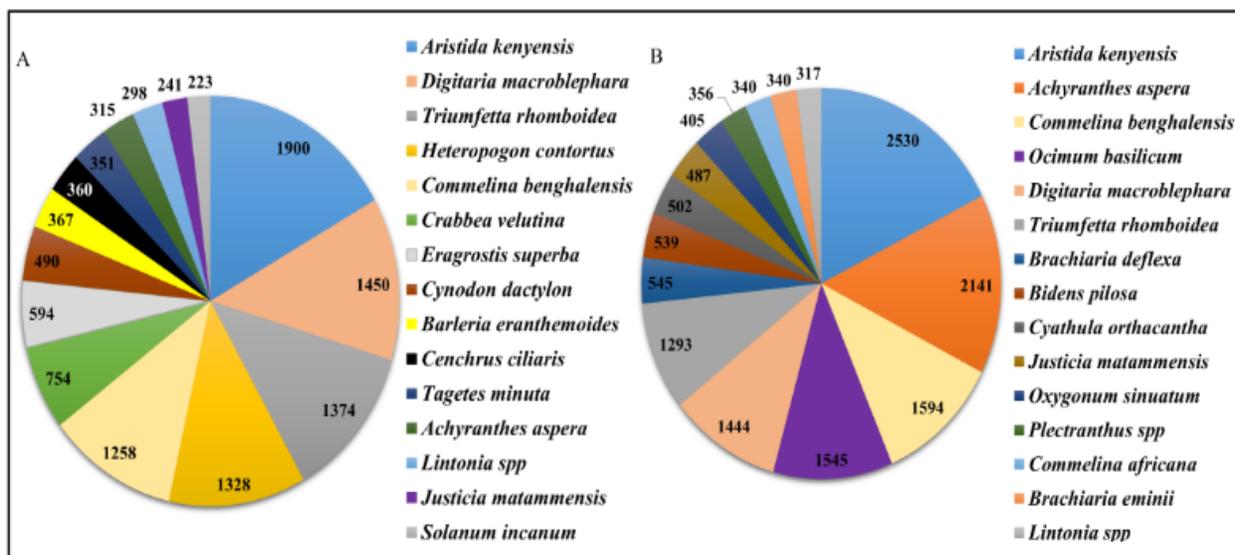

**Figure 6:** The most dominant families in Vumari (A) and Kisiwani (B) during the short rain season and Vumari (C) and Kisiwani (D) during the long rain season of 2021/2022.

A total of 6638 and 7017 plant species abundances were recorded during the short rainy season in both Vumari (study area I) and Kisiwani (study area II) wards respectively. *Triumfetta rhomboidea*, *Bidens Pilosa*, *Cynodon dactylon*, *Commelina Africana*, *Commelina benghalensis*, *Crabbea velutina*, *Brachiaria deflexa*, *Oxygonum sinuatum*, *Achyranthes aspera* and *Acanthospermum hispidum* were the most dominant plant species (Fig.7).

**Figure 7:** The most abundant plant species (top fifteen) in Vumari (A) and Kisiwani (B) during the short rain season

During the long rainy season, a total of 16816 and 19790 species abundances were recorded in Vumari and Kisiwani wards respectively. Where, *Aristida kenyensis*, *Digitaria macroblephara*, *Triumfetta rhomboidea*, *Heteropogon contortus*, *Commelina benghalensis*, *Crabbea velutina*, *Eragrostis superba*, *Cynodon dactylon*, *Achyranthes aspera*, *Ocimum basilicum*, *Brachiaria deflexa*, *Bidens Pilosa* and *Cyathula arcantha* were the most dominant plant species (Fig.8).

**Figure 8:** The most abundant plant species (top fifteen) in Vumari (A) and Kisiwani (B) during the long rainy season.

## 5.0 Foraging Preferences

The most visited plant families in both study areas during the short rainy season were *Malvaceae*, *Combretaceae*, *Rhamnaceae*, *Lamiaceae*, *Asteraceae*, *Cordiaceae*, *Poaceae*, and *Polygonaceae* (Fig. 9). During the long rainy season, the most visited plant families in both study areas were *Fabaceae*, *Lamiaceae*, *Euphorbiaceae*, *Poaceae*, *Malvaceae*, and *Amaranthaceae* (Fig. 9).

**Figure 6:** The most visited families in Vumari (A) and Kisiwani (B) during the short rain season and Vumari (C) and Kisiwani (D) during the long rain season of 2021/2022.

During assessing foraging preference, a total of 7,902 and 4,201 honeybees' visitations were recorded during the short rainy season of 2021/2022 in study areas I and II, respectively (Table 2), during the long rain season a total of 2,099 and 2,568 visits were recorded in study areas I and II, respectively, (Table 3).

**Table 2.** Honeybees' flower visitations during the short rain season of 2021/2022

Area I		Area II	
Plant species	No. of visitations	Plant species	No. of visitations
<i>Grewia bicolor</i>	2761	<i>Combretum schumannii</i>	1163
<i>Terminalia brownii</i>	2528	<i>Grewia bicolor</i>	1082
<i>Ziziphus mucronata</i>	1966	<i>Cordia monoica</i>	662
<i>Ocimum gratissimum</i>	295	<i>Oxygonum sinuatum</i>	461
<i>Aspilia mossambicensis</i>	233	<i>Urochloa panicoides</i>	445
<i>Oxygonum sinuatum</i>	50	<i>Acacia nilotica</i>	118
<i>Ocimum obovatum</i>	30	<i>Clerodendrum spp</i>	89
<i>Lantana camara</i>	16	<i>Waltheria indica</i>	82
<i>Commelina benghalensis</i>	10	<i>Combretum hereroense</i>	39
<i>Hypericum revolutum</i>	4	<i>Justicia matammensis</i>	21
<i>Eragrostis superba</i>	3	<i>Brachiaria deflexa</i>	18
<i>Justicia nyassana</i>	3	<i>Justicia eranthemoides</i>	13
		<i>Digera muricata</i>	4
		<i>Digitaria abyssinica</i>	3
		<i>Barleria eranthemoides</i>	1

**Table 3:** Honeybees' flower visitations during the long rain season of 2021/2022

Area I		Area II	
Plant species	No. of visitations	Plant species	No. of visitations
<i>Acacia mellifera</i>	1638	<i>Acacia mellifera</i>	1527
<i>Ocimum basilicum</i>	340	<i>Hoslundia opposita</i>	788
<i>Acalypha fruticosa</i>	38	<i>Ocimum basilicum</i>	146
<i>Heteropogon contortus</i>	26	<i>Acacia nilotica</i>	77
<i>Triumfetta rhomboidea</i>	19	<i>Achyranthes aspera</i>	14
<i>Vernonia galamensis</i>	11	<i>Acalypha fruticosa</i>	7
<i>Commelina benghalensis</i>	11	<i>Indigofera brevicalyx</i>	5
<i>Justicia matammensis</i>	6	<i>Eragrostis superba</i>	3
<i>Ocimum obovatum</i>	3	<i>Triumfetta rhomboidea</i>	1
<i>Panicum maximum</i>	3		
<i>Indigofera arrecta</i>	3		
<i>Gnidia eminii</i>	1		

In both rain seasons, different plants were identified as honeybees most preferred plants than others, also most of this preferred plant species were less abundant comparing to other plants. This observation reveals the concept that honeybees' foraging preference goes beyond plant species abundance (Irene 2009; Williams *et al.* 2011) thus, regardless of honeybees' survival depend much on plants as source of their potential resources, but also, they show preference and choice to certain species in a particular landscape (Aronne *et al.* 2012; Hawkins *et al.* 2015).

## 6.0 Training to Community and Research Findings Feedback

After the study, training was conducted to create awareness and communicate the information and recommendations drawn from the study findings to people/community around the study areas and others who live in places with similar geographical features as that of the study area in the district. In addition to local community, the training also involved different government officials

including District Beekeeping Officers and Conservational Officer (Community Development) from Mkomazi National Park. The training covered different issues that were identified and observed during the study and importantly covered the discussion on honeybees and plants conservation approaches. The training was delivered in two modes presentation of the results and findings found during the study and general knowledge on conservation and the relationship between plants and honeybee/other pollinators survival. Also, the training involved open discussion where people were given enough time to share their thoughts and skills acquired during training sessions and general knowledge.

**Figure 10:** Some of the participants preparing/testing the Rufford printed t-shirt just before the commence of the training session.

**Figure 11:** Some participants of the training after the session

## 7.0 Conclusion and Recommendation

Honeybees' existence and the sustainability of beekeeping industry depend much on a healthier and diversified ecosystem. The scarcity of preferred plant species in the study areas and other beekeeping potential areas compromises their existence and accelerates their decline. Information on the abundance and availability of plant species found in an area is crucial for their conservation, knowing what bees prefer gives a wide range of conserving such plants and ensures steady supply of bees' and other pollinators resources. From this study it has found that, plants that bees prefer the most across both rain seasons are less abundant in an area, therefore this necessitates conservation implications in both areas, including more knowledge and awareness campaigns on plant conservation, also the relationship and role of plants on honeybees' survival.

Furthermore, since beekeeping activities has been reported to be advantageous not only to the ecosystem but also in play a key role in income generation to individuals participating in the activities, therefore much emphasis and facilitation should be placed to increases people engagement and participation in the activities.
